## **Cache Memories**

- Cache memories are small, fast SRAM-based memories managed automatically in hardware.
  - Hold frequently accessed blocks of main memory
- CPU looks first for data in caches (e.g., L1, L2, and L3), then in main memory.
- Typical system structure:

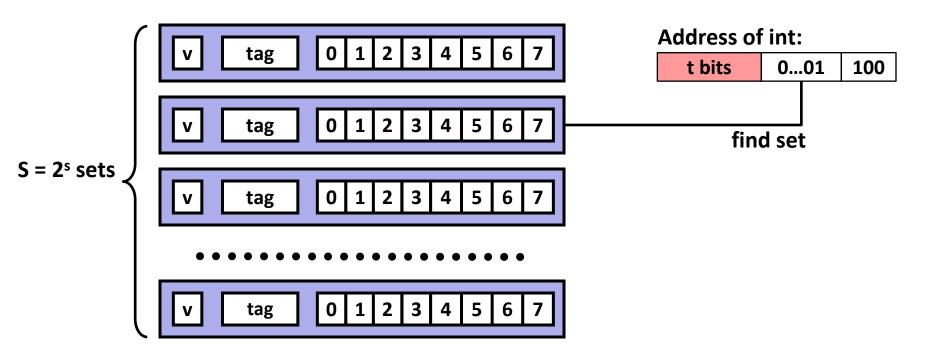

# General Cache Organization (S, E, B)

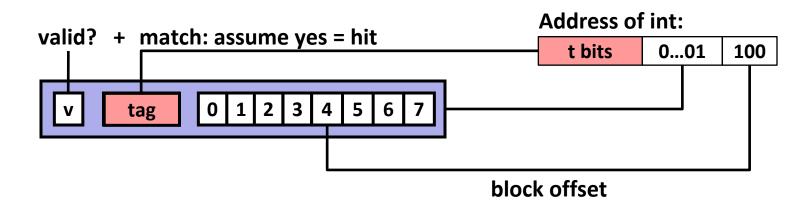

# **Example: Direct Mapped Cache (E = 1)**

Direct mapped: One line per set Assume: cache block size 8 bytes

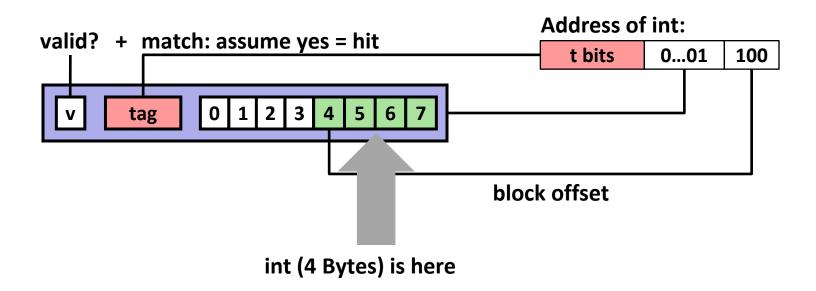

# **Example: Direct Mapped Cache (E = 1)**

Direct mapped: One line per set Assume: cache block size 8 bytes

# **Example: Direct Mapped Cache (E = 1)**

Direct mapped: One line per set Assume: cache block size 8 bytes

No match: old line is evicted and replaced

# **Direct-Mapped Cache Simulation**

t=1	s=2	b=1
Х	XX	Х

M=16 byte addresses, B=2 bytes/block, S=4 sets, E=1 Blocks/set

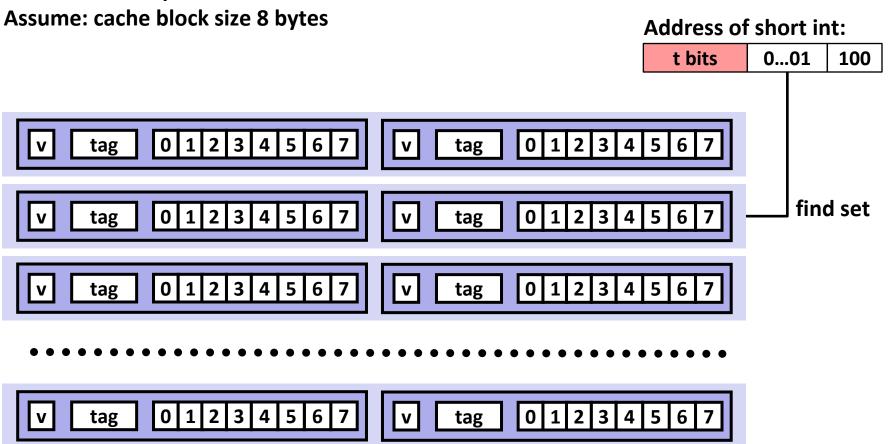

Address trace (reads, one byte per read):

0	[0 <u>00</u> 0 <sub>2</sub> ],	miss
1	[0 <u>00</u> 1 <sub>2</sub> ],	hit
7	[0 <u>11</u> 1 <sub>2</sub> ],	miss
8	$[1000_{2}],$	miss
0	[0000]	miss

	V	Tag	Block
Set 0	1	0	M[0-1]
Set 1			
Set 2			
Set 3	1	0	M[6-7]

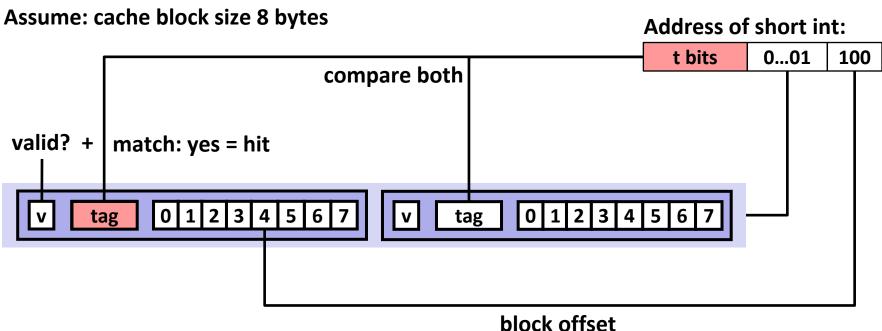

# E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

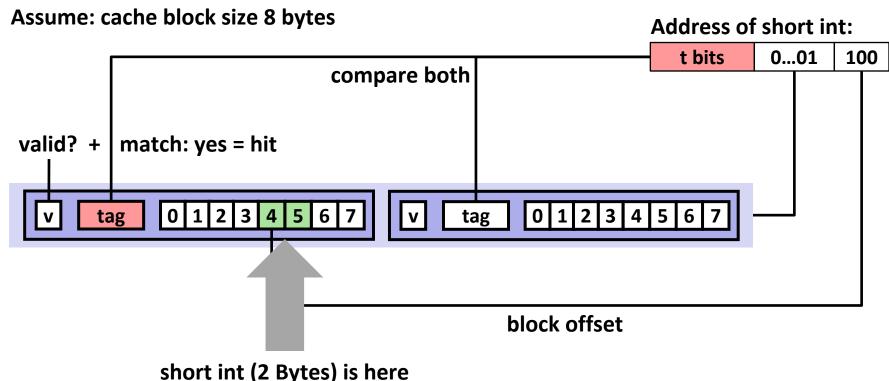

# E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

# E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

### No match:

- One line in set is selected for eviction and replacement
- •Replacement policies: random, least recently used (LRU), ...

# 2-Way Set Associative Cache Simulation

t=2	s=1	b=1
XX	Х	Х

## What about writes?

### Multiple copies of data exist:

- L1, L2, Main Memory, Disk
- What to do on a write-hit?
  - Write-through (write immediately to memory)
  - Write-back (defer write to memory until replacement of line)
    - Need a dirty bit (line different from memory or not)

### What to do on a write-miss?

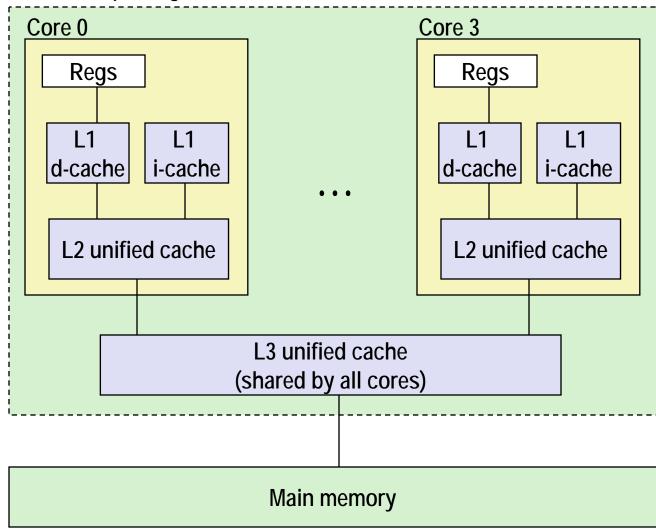

- Write-allocate (load into cache, update line in cache)
  - Good if more writes to the location follow
- No-write-allocate (writes immediately to memory)

### Typical

- Write-through + No-write-allocate
- Write-back + Write-allocate

# **Intel Core i7 Cache Hierarchy**

### Processor package

### L1 i-cache and d-cache:

32 KB, 8-way, Access: 4 cycles

### L2 unified cache:

256 KB, 8-way, Access: 11 cycles

### L3 unified cache:

8 MB, 16-way, Access: 30-40 cycles

**Block size**: 64 bytes for

all caches.

# **Cache Performance Metrics**

### Miss Rate

- Fraction of memory references not found in cache (misses / accesses)
   = 1 hit rate
- Typical numbers (in percentages):
  - 3-10% for L1
  - can be quite small (e.g., < 1%) for L2, depending on size, etc.</li>

### Hit Time

- Time to deliver a line in the cache to the processor
  - includes time to determine whether the line is in the cache
- Typical numbers:
  - 1-2 clock cycle for L1
  - 5-20 clock cycles for L2

### Miss Penalty

- Additional time required because of a miss
  - typically 50-200 cycles for main memory (Trend: increasing!)

## Lets think about those numbers

- Huge difference between a hit and a miss
  - Could be 100x, if just L1 and main memory
- Would you believe 99% hits is twice as good as 97%?
  - Consider: cache hit time of 1 cycle miss penalty of 100 cycles
  - Average access time:

```
97% hits: 1 cycle + 0.03 * 100 cycles = 4 cycles
99% hits: 1 cycle + 0.01 * 100 cycles = 2 cycles
```

■ This is why "miss rate" is used instead of "hit rate"

# **Writing Cache Friendly Code**

- Make the common case go fast
  - Focus on the inner loops of the core functions
- Minimize the misses in the inner loops
  - Repeated references to variables are good (temporal locality)
  - Stride-1 reference patterns are good (spatial locality)

Key idea: Our qualitative notion of locality is quantified through our understanding of cache memories.

# **Today**

- Cache organization and operation
- Performance impact of caches
  - The memory mountain
  - Rearranging loops to improve spatial locality
  - Using blocking to improve temporal locality

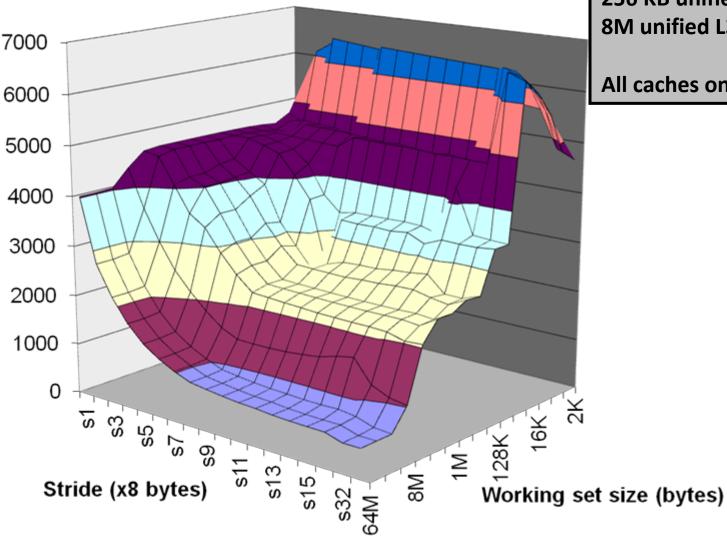

# **The Memory Mountain**

- Read throughput (read bandwidth)
  - Number of bytes read from memory per second (MB/s)
- Memory mountain: Measured read throughput as a function of spatial and temporal locality.
  - Compact way to characterize memory system performance.

# **Memory Mountain Test Function**

```
/* The test function */
void test(int elems, int stride) {
    int i, result = 0;
   volatile int sink;
    for (i = 0; i < elems; i += stride)
       result += data[i];
    sink = result; /* So compiler doesn't optimize away the loop */
/* Run test(elems, stride) and return read throughput (MB/s) */
double run(int size, int stride, double Mhz)
   double cycles;
    int elems = size / sizeof(int);
   test(elems, stride);
                                           /* warm up the cache */
   cycles = fcyc2(test, elems, stride, 0); /* call test(elems, stride) */
   return (size / stride) / (cycles / Mhz); /* convert cycles to MB/s */
```

# Miss Rate Analysis for Matrix Multiply

### Assume:

- Line size = 32B (big enough for four 64-bit words)
- Matrix dimension (N) is very large
  - Approximate 1/N as 0.0
- Cache is not even big enough to hold multiple rows

### Analysis Method:

Look at access pattern of inner loop

# **Matrix Multiplication Example**

### Description:

- Multiply N x N matrices
- O(N³) total operations
- N reads per source element
- N values summed per destination
  - but may be able to hold in register

```
/* ijk */
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0; ←
    for (k=0; k<n; k++)
        sum += a[i][k] * b[k][j];
    c[i][j] = sum;
    }
}
```

# Layout of C Arrays in Memory (review)

- C arrays allocated in row-major order
  - each row in contiguous memory locations
- Stepping through columns in one row:

```
for (i = 0; i < N; i++)
sum += a[0][i];</pre>
```

- accesses successive elements
- if block size (B) > 4 bytes, exploit spatial locality
  - compulsory miss rate = 4 bytes / B
- Stepping through rows in one column:

```
for (i = 0; i < n; i++)
sum += a[i][0];</pre>
```

- accesses distant elements
- no spatial locality!
  - compulsory miss rate = 1 (i.e. 100%)

# **Matrix Multiplication (ijk)**

```
/* ijk */
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0;
    for (k=0; k<n; k++)
        sum += a[i][k] * b[k][j];
    c[i][j] = sum;
  }
}</pre>
```

```
Inner loop:

(*,j)

(i,*)

    c[i][j] += a[i][k] * r;
  }
}</pre>
```

# Inner loop: (\*,k)

### Misses per inner loop iteration:

<u>A</u>	<u>B</u>	<u>C</u>
1.0	0.0	1.0

# **Summary of Matrix Multiplication**

```
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0;
  for (k=0; k<n; k++)
    sum += a[i][k] * b[k][j];
  c[i][j] = sum;
}
}</pre>
```

```
for (k=0; k<n; k++) {
  for (i=0; i<n; i++) {
    r = a[i][k];
  for (j=0; j<n; j++)
    c[i][j] += r * b[k][j];
  }
}</pre>
```

```
for (j=0; j<n; j++) {
  for (k=0; k<n; k++) {
    r = b[k][j];
    for (i=0; i<n; i++)
    c[i][j] += a[i][k] * r;
}</pre>
```

### ijk (& jik):

- 2 loads, 0 stores
- misses/iter = **1.25**

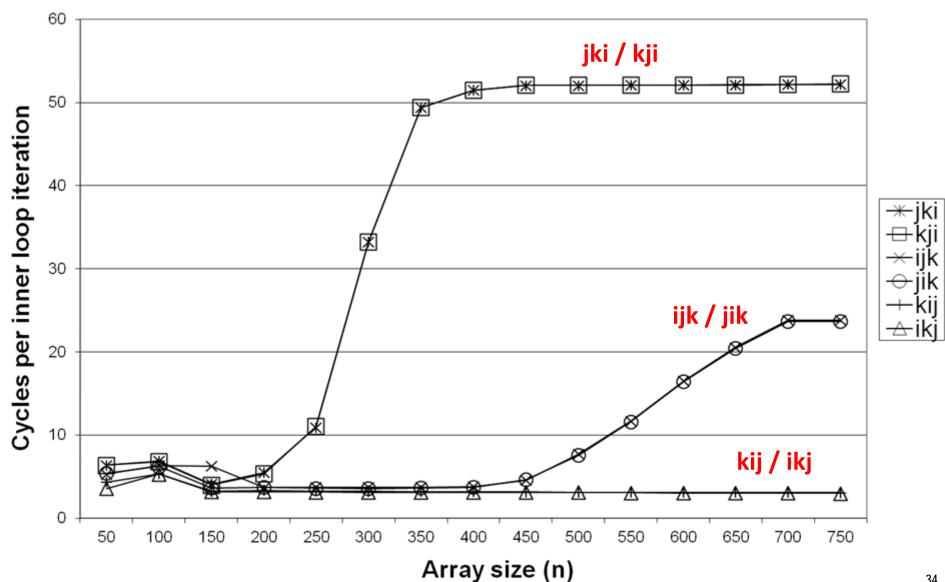

### kij (& ikj):

- 2 loads, 1 store
- misses/iter = **0.5**

### jki (& kji):

- 2 loads, 1 store
- misses/iter = **2.0**

# **Core i7 Matrix Multiply Performance**

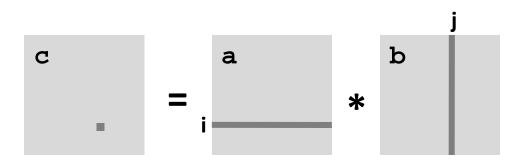

# **Today**

- Cache organization and operation
- Performance impact of caches
  - The memory mountain
  - Rearranging loops to improve spatial locality
  - Using blocking to improve temporal locality

# **Example: Matrix Multiplication**

```
c = (double *) calloc(sizeof(double), n*n);

/* Multiply n x n matrices a and b */
void mmm(double *a, double *b, double *c, int n) {
   int i, j, k;
   for (i = 0; i < n; i++)
        for (j = 0; j < n; j++)
        for (k = 0; k < n; k++)
        c[i*n+j] += a[i*n + k]*b[k*n + j];
}</pre>
```

# **Cache Miss Analysis**

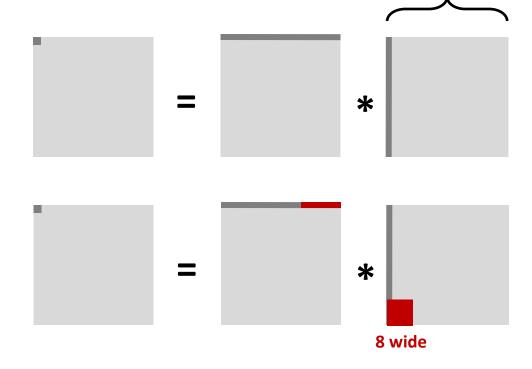

### Assume:

- Matrix elements are doubles
- Cache block = 8 doubles
- Cache size C << n (much smaller than n)</li>

### First iteration:

- n/8 + n = 9n/8 misses

Afterwards in cache: (schematic)

n

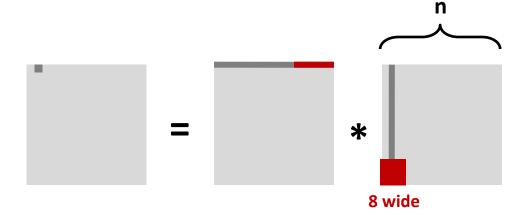

# **Cache Miss Analysis**

### Assume:

- Matrix elements are doubles
- Cache block = 8 doubles
- Cache size C << n (much smaller than n)</li>

### Second iteration:

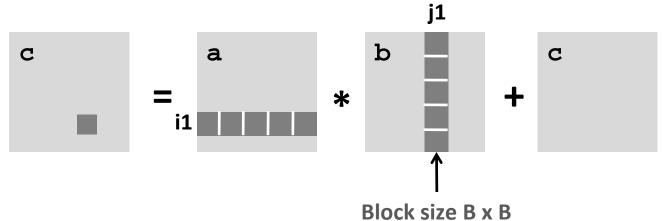

Again: n/8 + n = 9n/8 misses

### Total misses:

•  $9n/8 * n^2 = (9/8) * n^3$ 

# **Blocked Matrix Multiplication**

# **Cache Miss Analysis**

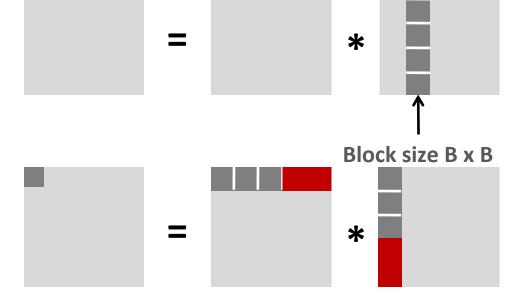

### Assume:

- Cache block = 8 doubles
- Cache size C << n (much smaller than n)</li>
- Three blocks fit into cache: 3B<sup>2</sup> < C</p>

### First (block) iteration:

- B<sup>2</sup>/8 misses for each block
- 2n/B \* B²/8 = nB/4 (omitting matrix c)

n/B blocks

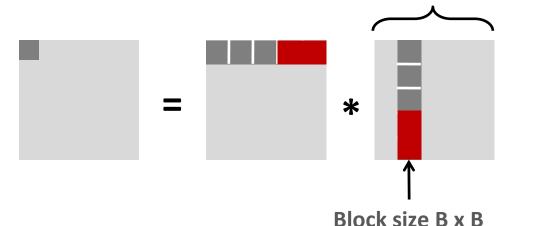

# **Cache Miss Analysis**

### Assume:

- Cache block = 8 doubles
- Cache size C << n (much smaller than n)</li>
- Three blocks fit into cache: 3B<sup>2</sup> < C</p>

### Second (block) iteration:

- Same as first iteration
- 2n/B \* B<sup>2</sup>/8 = nB/4

### Total misses:

 $\blacksquare$  nB/4 \* (n/B)<sup>2</sup> = n<sup>3</sup>/(4B)

n/B blocks

# **Summary**

- No blocking: (9/8) \* n³
- Blocking: 1/(4B) \* n³
- Suggest largest possible block size B, but limit 3B<sup>2</sup> < C!
- Reason for dramatic difference:
  - Matrix multiplication has inherent temporal locality:
    - Input data: 3n<sup>2</sup>, computation 2n<sup>3</sup>
    - Every array elements used O(n) times!
  - But program has to be written properly

# **Concluding Observations**

### Programmer can optimize for cache performance

- How data structures are organized
- How data are accessed
  - Nested loop structure
  - Blocking is a general technique

### All systems favor "cache friendly code"

- Getting absolute optimum performance is very platform specific
  - Cache sizes, line sizes, associativities, etc.
- Can get most of the advantage with generic code
  - Keep working set reasonably small (temporal locality)
  - Use small strides (spatial locality)
